ABSTRACT

Many eHealth innovation projects have emerged in the last few years, but most of them remain in a permanent pilot state, which is a growing concern in the management literature. The purpose of this study is to improve the understanding of the organizational capabilities that eHealth innovation projects require after the pilot state. The analysis follows an inductive theory building process comprising two qualitative studies. The first study derives propositions relating organizational capabilities to the implementation of eHealth projects from interviews with five experts in the area. Four capabilities emerge from the interviews: evaluation, collaborative leadership, stakeholder networking, and organizational flexibility. A second study validates the propositions analyzing seven eHealth projects that have reached implementation. This research also provides insight for managers of eHealth projects on how to define strategies to take their projects from pilot to real implementations, avoiding the so called “plague of pilots.”

Keywords: Organizational capabilities, Innovation projects, eHealth, Inductive theory building

1. Introduction

Healthcare systems in the Western world are confronting a significant pressure to reduce costs while improving last decades' quality of health service delivery. Several factors, such as an aging population, increasing mobility of patients, or lack of qualified health works, complicate the fulfillment of this purpose (Hedberg & Morosi, 2015). In addition, society expects solving today's problems through the extensive use of information and communication technologies (ICT) in healthcare; thus, Eysenbach (2001) introduced the term eHealth, which emerges as a silver bullet for achieving cost savings, efficiency, and quality in healthcare (Car, Black, Anandan, Cresswell, & Pagliari, 2008).

Many eHealth innovation projects have emerged in the last few years, but most of them remain in a permanent pilot state, which is a growing concern among researchers and policymakers. Scholars have identified the need to uncover mechanisms that help in achieving successful eHealth implementation (Andreassen, Kjekshus, & Tjora, 2015). Previous work identifies capabilities that organizations need to innovate and, more specifically, to co create value and knowledge with other stakeholders in innovation projects (Den Hertog, Van der Aa, & de Jong, 2010; Kazadi, Lievens, & Mahr, 2016; Sharma, Conduit, & Hill, 2014). However, the scientific literature on the required capabilities to implement innovation projects after the pilot stage is scarce.

The purpose of this study is to improve the understanding of the organizational capabilities necessary in innovation projects after the pilot state, focusing on eHealth projects. Organizational capabilities are bundles of skills and accumulated knowledge that enable companies to coordinate activities and use their assets (Day, 1994). These capabilities allow companies to respond quickly to changing customer preferences and creating a competitive advantage. Therefore, understanding the organizational capabilities that a company needs to lead the successful implementation of innovation projects in general, and eHealth projects in particular, is of great theoretical and practical importance.

This study aims to respond to the following research question: How do organizational capabilities contribute to take eHealth innovation projects from a pilot stage to a real implementation?

In answering the above research question, the study examines Kurt Lewin's (1945) contribution to science and follows an inductive theory building process comprising two qualitative studies. The first study derives propositions about organizational capabilities in eHealth from five interviews with eHealth experts. A second study validates the propositions by analyzing seven implemented eHealth projects.

The primary contribution of this study is explaining the organizational capabilities required for taking eHealth innovation projects from pilot to the implementation stage. The study also provides relevant insight for managers of eHealth projects and policy makers to define strategies to take their projects from pilot to real implementations, avoiding the so called “plague of pilots” (Andreassen et al., 2015).

The remainder of this research has the following structure. Section 2 describes antecedents of organizational capabilities through a review of the literature and the problem of the plague of pilots in eHealth projects. Section 3 describes the research method and the data collection.

Section 4 presents the main findings, and Section 5 discusses conclusions and research limitations.

2. Literature review

The resource based view of the firm (RBV) posits that the combination of heterogeneous resources with the firm's inner knowledge is a key driver of competitive advantage (Barney, 1991). This combination allows companies to generate knowledge that translates into innovation, which is difficult to diagnose and to replicate by competitors (Teece, 2014). This approach emphasizes that resources are easily transferable between organizations (Wu, Chen, & Jiao, 2016); thus, companies need to transform their resources into capabilities that allow them to achieve superior performance by weaving employees' tacit knowledge of the organization, which is more difficult to imitate and transfer (Makadok, 2001).

Companies require organizational, static, and dynamic capabilities to efficiently respond to changes in their environment; these capabilities should be part of the strategic plan of the company (O'Connor, 2008). Developing organizational capacities requires changes in the structures of power (Francis & Bessant, 2005) and in the activities related to knowledge and learning (Madhavan & Grover, 1998). Christensen (1997) described the organizational capabilities as a multidimensional construct that includes factors such as human, technologic, and material resources, and processes and criteria for decision making.

For companies, the innovative capability in changing environments is vital (Calantone, Cavusgil, & Zhao, 2002; Romijn & Albaladejo, 2002). The capability to innovate is the capability to generate and create new knowledge in the collective creation of value (Le Masson, Weil, & Hatchuel, 2010), which stems from the organizational capabilities of the firm (Grant, 1996). Previous work identifies organizational capabilities related to innovation in knowledge co creation (Kazadi et al., 2016), radical innovation (Forés & Camisón, 2016), value co creation (Galvagno & Dalli, 2014), and customer value (Martelo, Barroso, & Cepeda, 2013), among others.

A systematic review of the literature on the implementation of eHealth projects shows that methodological quality in this area is poor and provides little information on the ways in which managers and other users understand of eHealth systems (Mair et al., 2012). The so called "plague of pilots" exacerbates the situation; "plague of pilots" is a term that Wyatt and Sullivan (2005) introduced to refer to the fact that many eHealth projects run as non permanent test projects rather than as normal practice. The literature on the topic points out that eHealth projects seem to meet the criteria for technical success, "yet fail to become part of every day clinical routine" (de Bont & Bal, 2008, p. 1). In previous work, scholars determine as potential reason for such a problem, among others, the failure of adapting the individual or organization to new eHealth required management structures (Broens, Vollenbroek Hutten, Hermens, van Halteren, & Nieuwenhuis, 2007).

Table 1 shows the main organizational capabilities related to innovation that the literature identifies; the analysis uses them as the starting point to study capabilities in eHealth innovation projects.

3. Methods

This study employs an analytic induction method (Patton, 2002) to design a theory through a case study (Gomm, Hammersley, & Foster, 2000), using data from two qualitative studies. The method is appropriate to analyze the research questions, allowing integrating various sources of information inductively (Eisenhardt, 1989; Woodside & Wilson, 2003). The case method has also proved its suitability for process analysis, useful in information systems research (Miles, Huberman, & Saldana, 2013). Although the results of this method are difficult to generalize, the method allows examining certain propositions (Yin, 1994). Drawing from organizational capabilities, the study applies a theory development approach consistent with what Gregor

(2006) referred to as "theory for explaining." Using this process oriented narrative (Van de Ven & Poole, 2005), the study explains how organizational capabilities contribute in transitioning eHealth innovation projects from pilot to real implementation.

3.1. Data collection and analysis

The study collects all data in Spain; this country offers an interesting opportunity because of its progress in eHealth, according to international records, during the time of a financial crisis. Since the eighties of last century, the Spanish national health system offers virtually universal coverage, including a variety of services through a wide network of hospitals and health centers, following a decentralized relatively low cost model compared to other European countries (Borkan, Eaton, Novillo Ortiz, Corte, & Jadad, 2010).

Spain is among the leading countries in Europe in relation to making appointments with doctors through Internet. In 2014, 27.5% of Spanish citizens have concluded appointments in this way, placing Spain in the third position according to Digital Agenda Scoreboard of the European Commission. In addition, Spain obtained the fourth position across the European Union in the compound of electronic records of information in primary care (Codagnone & Lupiañez Villanueva, 2013), and the country ranked second in Europe in access to health information using mobile phones (Lupiañez, Maghiros, & Abadie, 2013).

The first study included interviews with five experts in eHealth from the government and the private sectors, previously involved in the implementation of eHealth innovation projects with different rates of success (Table 2). The interviews are face to face or by phone, with a duration of 60 min on average. The study uses the recordings and transcriptions of all interviews. The interviews consist of a semi structured questionnaire that, after a brief introduction to the study, asks about the participants' opinions and knowledge on the "plague of pilots," and about the key capabilities for transitioning eHealth pilots into projects, using as starting point the capabilities appearing in the literature review. The study also obtains additional data from reports from the United Nation, European Commission, and the Spanish Health Informatics Society, among other sources. The analysis applied inductive theory building to the data from the first stage, which results in

Table 2
Experts in eHealth interviewed in the first study and their profile.

Experts	Profile	Years of experience
Expert 1	B.Sc. in Political Science and Sociology, Former Regional Minister of Health, Subdirector for health affairs in a national public agency	30
Expert 2	B.Sc. in Sociology, M.Sc. in Data Analysis, Manager eHealth research projects, Consultant in eHealth	15
Expert 3	Ph.D. in Medicine, Former Director Business Development in a pharmaceutical company, Consultant in eHealth	24
Expert 4	B.Sc. in Business Administration, Former Regional Minister of Health, Member Advisory Board in eHealth companies	17
Expert 5	B.Sc. in Business Administration, Former Director Digital Solutions in a pharmaceutical company, Analytics Corporate Director in an health insurance company	14

propositions relating organizational capabilities to the implementation of eHealth innovation projects.

The second study validates propositions using a multiple case study (Eisenhardt, 1989) comprising seven eHealth innovation projects that have reached an implementation stage (Table 3). Eleven interviewees covered representative stakeholders of eHealth: health managers, health professionals, project developers, and consultants. Sample selection follows a strategy similar to the studies on ICT projects in the health sector (Andreassen et al., 2015). The 11 in depth semi structured interviews are face to face or by phone, with durations of 40–60 min in average, and the interview provided adapted scripts to each respondent profile. All interviews are on tape and transcript (Table 4).

The unit of analysis in both studies is the interview transcripts, as well as reflections on various documents the respondents provide and other publicly available sources (websites, magazines, and press articles) of the last 2 years. Participants in the research are aware of the anonymity of their views and projects' case studies, which enhances respondents' expression of their opinions (Drumwright & Murphy, 2004).

The analysis triangulates the data (Yin, 1994) of the various data sources. First, the study conducts a thematic analysis (Boyatzis, 1998), coding the data using the capabilities obtained from the literature review. To refine the results, the research process iteratively feeds back information from interviews and from other sources (Eisenhardt, 1989).

4. Findings

4.1. Emerging organizational capabilities

4.1.1. Evaluation capability

Evaluation capability comprises performing an effective evaluation that meets the accepted standards of a discipline (McDonald, Rogers, & Kefford, 2003). All experts highlight the importance of having an

Table 4
Stakeholders in the second study and their profile.

Stakeholder	Profile	Number of interviews
Health managers	General director of information systems, graduated in computer science Director of public hospital, graduated in Medicine	2
Health professionals	Medical doctor, specialist in pediatrics Medical doctor, specialist in dermatology Medical doctor, specialist in traumatology Medical doctor, specialist in family and community health	4
eHealth developers	Telecommunications engineer, specializing in IT applied to the health sector Informatics engineer	2
eHealth consultants	Medical doctor, specialist in surgery IT health director at consulting firm, graduated in business administration Industrial engineer, specialized in eHealth	3

evaluation capability for the implementation of eHealth projects. The evaluation should cover patient needs, include scientific personnel, and take into consideration the organizational context of implementation of the innovation project:

In eHealth projects, the first thing to do is to detect the patient's needs (...), to consider which are the patients' pain points. (Expert 5)

The projects require having a scientific and technical evaluation, which usually comes from a health professional. (Expert 4)

One needs to know the organization where the innovation is going to be applied, as well as its operation, so that one can find a favorable context in which to integrate the innovation. (Expert 1)

When evaluating an eHealth project, one needs to accumulate knowledge about the market, especially knowledge about patients, as well as interpreting and acting upon the knowledge obtained (Day, 2011), which implies a deep understanding of the market needs. All these comments lead the study to formulate the following proposition:

Proposition 1. Evaluation capability positively affects the implementation of eHealth innovation projects

4.1.2. Collaborative leadership capability

Collaborative leadership refers to the integration of ideas and the development of partnerships to find best practices and improvements in business processes (VanVactor, 2012). Experts express in the interviews

Table 3
Description of eHealth projects in the second study.

Project	Description	Type of project
Project 1	Web-based information system that displays clinical patient information such as medical history in primary care, specialized reports from different care services, outstanding appointments, and inter-clinical appointments, among others.	Electronic records management
Project 2	Public innovation infrastructure aimed at improving the health care of chronically fragile and dependent patients.	Tele-medicine
Project 3	Monitoring patients with heart disease by wearable that can record and monitor patients with cardiac pathology in order to improve diagnosis and therapy of patients.	Wearables
Project 4	Mobile tool for physicians' consultation and reference. Includes summaries of recent articles published in journals of higher impact factor and a clinically relevant drug database that includes updated prices and regulation.	Mobile health
Project 5	Platform for diabetes self-management by the patient, and for monitoring, analyzing, and assessing the state of the same by the doctor.	Mobile health
Project 6	Platform for cognitive rehabilitation of people with brain damage by using learning games defined by therapists.	eHealth
Project 7	Platform created to facilitate communication between primary care physicians and hospitals regarding the quality of care, professional competence and training, and efficiency of the health system.	Tele-medicine

the need for collaboration in eHealth projects and having a collaborative leadership among stakeholders as key for an implementation:

Health today is an ecosystem with various parties making decisions (...) Everything we do has to be collaborative (...) We have to develop solutions co created by the patient and his eco system. (Expert 5)

One needs to work with the organization, understood as a set of people who produce the service in question, so that they can take ownership of the innovation (...) It is needed a collaborative approach that takes into account all stakeholders. (Expert 1)

Collaborative leadership arises from an organizational culture based on the information that allows taking decisions and communicating them transparently (VanVactor, 2012). The following proposition follows the experts' comments.

Proposition 2. Collaborative leadership facilitates the implementation of eHealth innovation projects.

4.1.3. Stakeholder networking capability

The post pilot phase requires the creation of networks of stakeholders, who are not equally necessary as those who participate during the eHealth project development phase. Network creation may focus on the diffusion of project results among other stakeholders to attract additional funding or to avoid duplication of work and transmit the accumulated experience, which emerges from the experts' interviews:

It is essential the transmission of the results of the innovation project ... in different areas and networks, whether corporate or social. (Expert 1)

During the dissemination of project results, we cannot ignore the role that some stakeholders can play, who can act as project financiers. (Expert 2)

We may need additional funding, and this involves going to talk to potential financiers like the pharmaceutical industry and the laboratories. (Expert 3)

Project managers need to develop the capability of attracting other stakeholders that may provide additional resources for moving the projects from pilot to implementation. The following proposition arises from the above comments:

Proposition 3. In eHealth innovation projects, stakeholder networking capability in the post pilot phase helps in the integration of new resources.

4.1.4. Organizational flexibility capability

In this research, the concept of organizational flexibility follows Teece, Pisano, and Shuen (1997), considering organizational flexibility as a combination of a repertoire of organizational and managerial capabilities that allow organizations to adapt quickly under environmental shifts. The interviews show the need of organizational flexibility in several dimensions, such as the operating business model or the diffusion of the knowledge. For instance, Expert 4 highlights the importance of having a flexible business model:

It's important the capacity to develop the business model (...) I advised project X, their first approach was "we want to license the software." I said, "do not license the software because it is difficult to protect the intellectual property rights." We set out to follow a SaaS model (...) which involved talking to the device's manufacturer, and

included renting rather than selling the device, and the cost was included in the payment for use. (Expert 4)

By contrast, Expert 1 emphasizes the need of flexibility in the innovation diffusion:

It's important to know how healthcare organizations work, which are the key roles, and from there to evolve to a more flexible position so that they can apply the new knowledge, the new innovation. (Expert 1)

Organizational flexibility capability ensures that the services are what users really need, having a positive influence on the acquisition of new knowledge (Sharma et al., 2014). From the interviews arises the following proposition in relation to organizational flexibility:

Proposition 4. Organizational flexibility capability enables the implementation of eHealth innovation projects.

4.2. Validating the propositions in eHealth innovation projects

This part analyzes the seven eHealth cases using the four propositions. Case material coming from the stakeholders' interviews contributes to the propositions' discussion.

4.2.1. P1 evaluation capability positively affects the implementation of eHealth innovation projects

The need for scientific and technical evaluation emerges in the second study, particularly the importance of the scientific evaluation:

If there existed a cardiology app, it would be key that the National Society of Cardiology validated that all the contents are appropriate and updated ... We have a group of apps in production, we are fully responsible for them ... and we certified that these apps rely on analytics that are done in a hospital. (Health Manager 1)

In our case, we have medical advisors ... because in the end, if your application is intended for a medical audience, and it has been approved by a doctor, you may reach your target. (eHealth Developer 1)

[Evaluations] probably are going to be a work of medical associations; they have to give a seal of quality to [eHealth] apps. (Health Professional 3)

Implementing a pilot requires performing an evaluation, indicating that the pilot is meeting the needs of the patient, and that the pilot works with existing systems:

Our piloting approach focuses on the patient and integrating the pilot with existing systems ... which leads us to a single, fully integrated clinical history. (Health Manager 1)

4.2.2. P2 collaborative leadership facilitates the implementation of eHealth innovation projects

Collaboration emerges as the keyword in the second study, and several projects consider central to its success the promotion of collaboration among the different stakeholders involved in the project:

There are some interesting experiences of collaboration networks ... There are communities like X that have organized committees about tumors using collaborative tools. They can prepare a complex case with its images and documentation, and circulate it among various experts to discuss it. (eHealth Consultant 2)

Collaborative leadership emerges in the projects, in particular, in those involving user communities.

Our application gives recommendations for X [disease] related to diet, healthy life, etc.... One hundred doctors in Spain are using the system ... we also have an international advisory board with the top ten specialist from Spain and USA. (eHealth Developer 2)

4.2.3. P3 in eHealth innovation projects, stakeholder networking capability in the post pilot phase helps in the integration of new resources

Stakeholder networking capability is key for acquiring knowledge resources:

I have connected with projects in other countries, with professionals from other places to interchange comments and experiences about the project results, ... which has allowed me to get involved in things that otherwise would not be, and incorporate the knowledge in the projects. (Health Professional 4)

Open innovation assumes that firms can use external ideas as well as internal ones, and internal and external paths to market, because the firms aim to improve their technology (Chesbrough, 2006). Stakeholder networks play an important role in open innovation, in particular in knowledge co creation (Kazadi et al., 2016). The interviewees mention the application of open innovation to knowledge co creation in eHealth:

We, in the X project, ... develop what the community says ... it's an open innovation process in which the community itself gives ideas and tells you what you need and how you need it ... you try it for free before it sets the market ... and part of the success of our project is that. (eHealth Developer 2)

Furthermore, the importance of stakeholder networking and diffusion for obtaining additional investment for pilots is evident:

There is a need for more coordination networks and adequate dissemination of results: with the limited resources we have, it is not possible having uncoordinated eHealth projects between the different [autonomous] regions. (Health Manager 2)

The results indicate the importance of stakeholder networking to integrate resources, but the main resource to integrate them is knowledge.

4.2.4. P4 organizational flexibility capability enables the implementation of eHealth innovation projects

The medical context considers eHealth as a changing field, which evolves constantly and requires that people, processes, and products evolve too.

In a few years, we will monitor electrocardiograms and connect them to iPhone with very little money (...) if you can send this information to the cardiologist of a patient with bad heart, you will change his quality of life ... in coming years the number of devices that go online will increase (...). The technology must be adapted to each person (...). One has to adapt to the technological changes and to the [digital] literacy of the patients. (Health Professional 1)

Patients' needs contribute to updating eHealth projects:

[Specialists like me] digitize what we do every day (...). I'm turning information into a much more active patient monitoring system. I am developing logic trees that, as the patient is giving me information, I'll be giving them personalized answers. (Health Professional 4)

5. Conclusions

The research explores how organizational capabilities contribute in transitioning eHealth innovation projects from pilots to real implementations. Four propositions relating organizational capabilities

to the implementation of eHealth projects arise from the analysis. First, evaluation capability positively affects the implementation of eHealth innovation projects. The analysis shows that the evaluation capability should be as wide as possible, covering the patients' needs, a scientific/medical point of view, and the organizational context.

The second proposition states that collaborative leadership facilitates the implementation of eHealth projects. Experts see health today as an ecosystem with various parties taking decisions. In the center of such ecosystem is the patient because the patients and other members of the ecosystem co create many of the initiatives related to the eHealth project. The leader member exchange theory serves as basis for collaborative leadership, which posits that leadership occurs when leaders and followers are able to develop effective relationships and partnerships that result in influences (Uhl Bien, 2006). The study finds evidence of such effective relationships and partnerships in the eHealth projects, and the projects consider such type of strategic leadership in their success.

The third proposition relates stakeholder networking capability with the integration of new resources. Although the study finds evidence supporting this proposition, the results include some differences between the experts' view and the eHealth projects analyzed in relation to the type of new integrated resources. In the first study, experts emphasize stakeholder networking capability as key for attracting the necessary financial resources for the implementation of the project. Most eHealth projects use stakeholder networking capability for attracting new knowledge and consider this capability important for the success and sustainability of their projects. Dyer and Singh (1998) argued that relationships with partners outside the firm can enable company access to different additional resources, such as financial, intellectual, and human capital, supporting the opinions of both the experts and the eHealth projects.

The fourth proposition relates organizational flexibility capability with the implementation of eHealth projects. The study finds evidence supporting this relation. In particular, flexibility for updating the business model operation emerges as important for the projects. This result is in line with previous studies that recommend eHealth projects to include a business model description and a business case as part of their implementation strategy (van Limburg et al., 2011).

The main contribution of this work is the identification of the main capabilities required for taking eHealth innovation projects from pilots to real implementations. Of the four capabilities identified, evaluation capability rises as an essential one, with many respondents mentioning the lack of proper evaluation as the reason for failure in several eHealth initiatives.

A customer centric approach emerges from the research. Both the experts and the eHealth projects manifest that customers in this case, patients have taken a central role. This customer centricity is also evident in some of the identified capabilities: evaluation capability for eHealth projects should start "evaluating patients' needs," and patients should be the center of the ecosystem for collaborative leadership. Trust determines the establishment and maintenance of relationships between customers and service providers, playing a fundamental role in online environments (Urueña & Hidalgo, 2015) like eHealth projects.

Finally, the research has some limitations. As this study focuses exclusively in one country and one sector, future studies should examine the proposed capabilities from a broader context, including several countries and other sectors. Such research could lead to a more nuanced understanding of organizational capabilities in innovation projects.
